Outline

Goal: Describe a procedure for constructing diagrammatic presentations of categories of representations of Lie algebras and their quantum analogues.

Example: Type F_4

Overview:

- 1 Background: centralizers in classical types
- 2 String diagrams for monoidal categories
- 3 Example: The Brauer category
- 4 The diagrammatic F_4 category
- 5 The quantum diagrammatic F_4 category

Centralizers in type A

For $n \in \mathbb{N}$, let $V = \mathbb{C}^n$ be the natural $GL(n)$ -module.

The natural permutation action yields a surjective algebra homomorphism

$$\mathbb{C}\mathfrak{S}_r \twoheadrightarrow \text{End}_{GL(n)}(V^{\otimes r}).$$

This is part of **Schur–Weyl duality**.

If we want to include the dual module V^* , we have

$$\text{OB}_{r,s}(n) \twoheadrightarrow \text{End}_{GL(n)}(V^{\otimes r} \otimes (V^*)^{\otimes s}),$$

where $\text{OB}_{r,s}(n)$ is the **walled Brauer algebra** (or **oriented Brauer algebra**).

Centralizers in other types

Types BCD

The natural $O(n)$ -module V is **self-dual**. Let $n = \dim V$.

We have

$$B_r(n) \twoheadrightarrow \text{End}_{O(n)}(V^{\otimes r}),$$

where $B_r(n)$ is the **Brauer algebra**.

Similarly statement holds in the symplectic case.

Exceptional types

Less is known in exceptional types.

We will focus on the Lie algebra \mathfrak{f} of **type F_4** .

If V is the natural \mathfrak{f} -module, we want

$$?? \twoheadrightarrow \text{End}_{\mathfrak{f}}(V^{\otimes r})$$

Bigger picture

In fact, things become much more natural if we describe **more**.

General idea

Instead of only considering endomorphisms of $V^{\otimes r}$, we consider **all** morphisms $V^{\otimes r} \rightarrow V^{\otimes s}$ (and include dual V^* in type A).

Want a “nice” **monoidal category** \mathcal{C} , together with a full and essentially surjective monoidal functor

$$\mathcal{C} \rightarrow \mathfrak{g}\text{-mod.}$$

Desired features

- 1 \mathcal{C} should be easy to describe, e.g. want a **presentation** in terms of generators and relations.
- 2 Should recover centralizer statements when restricting to appropriate endomorphism spaces.

Strict monoidal categories

A **strict monoidal category** is a category \mathcal{C} equipped with

- a bifunctor (the **tensor product**) $\otimes: \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$, and
- a **unit object** $\mathbb{1}$,

such that, for objects A, B, C and morphisms f, g, h ,

- $(A \otimes B) \otimes C = A \otimes (B \otimes C)$,
- $\mathbb{1} \otimes A = A = A \otimes \mathbb{1}$,
- $(f \otimes g) \otimes h = f \otimes (g \otimes h)$,
- $1_{\mathbb{1}} \otimes f = f = f \otimes 1_{\mathbb{1}}$.

Remark: Non-strict monoidal categories

In a (not necessarily strict) **monoidal category**, the equalities above are replaced by isomorphism, and we impose some **coherence conditions**.

Every monoidal category is monoidally equivalent to a strict one.

Linear monoidal categories

For simplicity, we work over the ground field \mathbb{C} .

A **strict linear monoidal category** is a strict monoidal category such that

- each morphism space is a \mathbb{C} -module,
- composition of morphisms is \mathbb{C} -bilinear,
- tensor product of morphisms is \mathbb{C} -bilinear.

The interchange law

The axioms of a strict monoidal category imply the **interchange law**: For

$A_1 \xrightarrow{f} A_2$ and $B_1 \xrightarrow{g} B_2$, the following diagram commutes:

$$\begin{array}{ccc} A_1 \otimes B_1 & \xrightarrow{1 \otimes g} & A_1 \otimes B_2 \\ f \otimes 1 \downarrow & \searrow f \otimes g & \downarrow f \otimes 1 \\ A_2 \otimes B_1 & \xrightarrow{1 \otimes g} & A_2 \otimes B_2 \end{array}$$

String diagrams

Fix a strict monoidal category \mathcal{C} .

We will denote a morphism $f: A \rightarrow B$ by:

The **identity map** $1_A: A \rightarrow A$ is a string with no label:

We sometimes omit the object labels when they are clear or unimportant.

String diagrams

Composition is **vertical stacking** and tensor product is **horizontal juxtaposition**:

The **interchange law** then becomes:

A morphism $f: A_1 \otimes A_2 \rightarrow B_1 \otimes B_2$ can be depicted:

Example: Brauer category

Fix $n \in \mathbb{C}$. The Brauer category $\mathcal{B}(n)$ is the linear monoidal category defined as follows.

One generating object: $\mathbb{1}$

Three generating morphisms:

$$\cup: \mathbb{1} \rightarrow \mathbb{1}^{\otimes 2}, \quad \cap: \mathbb{1}^{\otimes 2} \rightarrow \mathbb{1}, \quad \times: \mathbb{1}^{\otimes 2} \rightarrow \mathbb{1}^{\otimes 2}.$$

Relations:

$$\begin{aligned} \text{Cup} &= \text{Cup}, & \text{Cross} &= \text{Cross}, & \text{Cap} &= \text{Cap} = \text{Cup}, \\ \text{Cap} &= \text{Cap}, & \text{Cap} &= \cap, & \text{Cap} &= n \mathbb{1} \end{aligned}$$

(We'll motivate these relations soon.)

Example: Brauer category

An arbitrary morphism in $\mathcal{B}(n)$ is a linear combination of **Brauer diagrams**.

E.g.

Composition: vertical “gluing”, replace closed components by a factor of n .

Tensor product: horizontal concatenation.

Example: Brauer category

Universal property

Any linear symmetric monoidal category \mathcal{C} with self-dual object V of dimension n admits a linear monoidal functor

$$\mathcal{B}(n) \rightarrow \mathcal{C}, \quad 1 \mapsto V.$$

Corollary

We have a linear monoidal functor ($V =$ natural module)

$$\mathcal{B}(n) \rightarrow \mathbf{O}(n)\text{-mod}, \quad 1 \mapsto V.$$

$$\times \mapsto (V^{\otimes 2} \rightarrow V^{\otimes 2}, \quad v \otimes w \mapsto w \otimes v),$$

$$\cap \mapsto (V^{\otimes 2} \rightarrow \mathbb{C}, \quad v \otimes w \mapsto \langle v, w \rangle),$$

$$\cup \mapsto (\mathbb{C} \rightarrow V^{\otimes 2}, \quad 1 \mapsto \sum_{v \in \mathbf{B}_V} v \otimes v),$$

where $\langle \cdot, \cdot \rangle$ is the bilinear form, and \mathbf{B}_V is an orthonormal basis.

Example: Brauer category

In fact, this functor is **full**. In particular, we recover the surjection

$$B_r(n) \cong \text{End}_{B(n)}(I^{\otimes r}) \twoheadrightarrow \text{End}_{O(n)}(V^{\otimes r}),$$

where $B_r(n)$ is the **Brauer algebra**.

Fact: Every f.d. $O(n)$ -module is a summand of $V^{\otimes r}$ for some r .

Philosophy

All homomorphisms between f.d. $O(n)$ -modules are built from the “flip” symmetry, the bilinear pairing, and its dual.

Similar statements are true in the **symplectic** case.

Understanding the relations

Nondegeneracy of the bilinear form gives the relation

$$\text{cap} = \text{cup}.$$

The left-hand side is the composition

$$\begin{aligned} V &\cong V \otimes \mathbb{C} \xrightarrow{1_V \otimes \cup} V \otimes V \otimes V \xrightarrow{\cap \otimes 1_V} \mathbb{C} \otimes V \cong V, \\ w &\mapsto w \otimes 1 \mapsto \sum_{v \in \mathbf{B}_V} w \otimes v \otimes v \mapsto \sum_{v \in \mathbf{B}_V} \langle w, v \rangle \otimes v \mapsto \sum_{v \in \mathbf{B}_V} \langle w, v \rangle v = w. \end{aligned}$$

Symmetry of the bilinear form gives the relation:

$$\text{cup} = \text{cap}$$

We also have

$$\text{bubble} : \mathbb{C} \rightarrow \mathbb{C}, \quad 1 \mapsto \sum_{v \in \mathbf{B}_V} \langle v, v \rangle = \dim V.$$

So the “bubble” corresponds to the **dimension** of the object V .

Understanding the relations

The remaining relations come from the fact that the flip map endows the category with the structure of a **symmetric monoidal category**.

Flip satisfies the relations of the symmetric group:

$$\begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} = \parallel, \quad \begin{array}{c} \diagup \diagdown \\ \diagup \diagdown \end{array} = \begin{array}{c} \diagdown \diagup \\ \diagdown \diagup \end{array}.$$

Naturality gives $\begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} = n \parallel$.

Composing on the bottom with $\parallel \times$ gives $\begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} = \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array}$.

A small endomorphism space ($n \geq 4$)

We have $V = V_{\omega_1}$ and $V^{\otimes 2} = V_{2\omega_1} \oplus V_{\omega_2} \oplus \mathbb{C}$.

Then $\text{End}_{O(n)}(V^{\otimes 2})$ is 3-dimensional, spanned by

$$\parallel, \quad \times, \quad \cup.$$

Goal

Goal

We want analogous results in **type F_4** .

Let \mathfrak{f} be the simple complex Lie algebra of type F_4 .

We want a linear monoidal category \mathcal{F} and a functor

$$\Phi: \mathcal{F} \rightarrow \mathfrak{f}\text{-mod},$$

such that

- \mathcal{F} has a simple presentation,
- Φ is **full** (surjective on morphisms),
- Φ is **essentially surjective** (surjective on isomorphism classes) after adding in summands.

Question

How do we find a presentation of \mathcal{F} using as little information about the representation theory of \mathfrak{f} as possible?

Important observations about F_4

Let $V = V_{\omega_4}$ be the smallest nontrivial simple \mathfrak{f} -module ($\dim V = 26$).

Facts

- V is self-dual.
- Every f.d. simple \mathfrak{f} -module is contained in $V^{\otimes r}$ for some $r \in \mathbb{N}$.
- We have

$$\begin{aligned} \dim \operatorname{Hom}_{\mathfrak{f}}(V, V) &= 1, & \dim \operatorname{Hom}_{\mathfrak{f}}(V^{\otimes 2}, V) &= 1, \\ \dim \operatorname{Hom}_{\mathfrak{f}}(V^{\otimes 2}, V^{\otimes 2}) &= 5, & \dim \operatorname{Hom}_{\mathfrak{f}}(V^{\otimes 2}, V^{\otimes 3}) &= 15. \end{aligned}$$

Note: $\operatorname{Hom}_{\mathfrak{f}}(V^{\otimes m}, V^{\otimes n}) \cong \operatorname{Hom}_{\mathfrak{f}}(V^{\otimes(m+n)}, \mathbb{C})$ for all $m, n \in \mathbb{N}$.

- We have a decomposition

$$V^{\otimes 2} = \mathbb{C} \oplus V \oplus V_{\omega_1} \oplus V_{\omega_3} \oplus V_{2\omega_4}.$$

Generators of the diagrammatic category

Generating object

We have one generating object I , corresponding to V .

Generating morphisms

$\text{Hom}_f(V^{\otimes 2}, \mathbb{C})$ and $\text{Hom}_f(\mathbb{C}, V^{\otimes 2})$ are spanned by

$$\cap: V \otimes V \rightarrow \mathbb{C} \quad \text{and} \quad \cup: \mathbb{C} \rightarrow V \otimes V.$$

$\text{Hom}_f(V^{\otimes 2}, V)$ is spanned by $\wedge: V^{\otimes 2} \rightarrow V$.

We have the **flip map**

$$\times: V^{\otimes 2} \rightarrow V^{\otimes 2}, \quad v \otimes w \mapsto w \otimes v.$$

Some initial relations

We have

$$\begin{array}{l}
 \text{nondegeneracy of the bilinear form on } V \\
 \dim \text{Hom}_{\mathfrak{f}}(V, V^{\otimes 2}) = 1 \\
 \text{symmetry of the bilinear form} \\
 \text{symmetry of the map } \text{Y}
 \end{array}$$

The flip map \times endows $\mathfrak{f}\text{-mod}$ with the structure of a symmetric monoidal category:

More initial relations

Since $\dim \text{Hom}_f(V, V) = 1$, we have

$$\begin{array}{c} | \\ \diamond \\ | \end{array} = \alpha \quad \Big| \quad \text{for some } \alpha \in \mathbb{C}.$$

Since $\dim \text{Hom}_f(\mathbb{C}, \mathbb{C}) = 1$, we have

$$\bigcirc = n1_{\mathbb{1}} \quad \text{for some } n \in \mathbb{C}.$$

(In fact, $n = \dim V = 26$.)

Since $\dim \text{Hom}_f(\mathbb{C}, V) = 0$, we have

$$\begin{array}{c} | \\ \bigcirc \end{array} = 0.$$

A preliminary category

For $\alpha, n \in \mathbb{C}$, $\mathcal{T} = \mathcal{T}_{\alpha, n}$ is the linear monoidal category defined as follows.

One generating object: $\mathbb{1}$ Four generating morphisms: $\cup, \cap, \times, \circ$

Relations:

$$\begin{aligned}
 \cup = | = \cap, \quad \cup := \cup = \cup, \quad \cap = \cap, \\
 \times = ||, \quad \times = \times, \quad \cup \cap = \cup \cap, \quad \times \times = \cup \cap, \\
 \cup = \cap, \quad \cup = \cup, \quad \cap = \alpha |, \quad \circ = n \mathbb{1}_{\mathbb{1}}, \quad \circ = 0.
 \end{aligned}$$

Notes

- Can scale \cup and \cap to reduce to case $\alpha = 1$.
- Category is strict pivotal (isotopy invariance), so we can define

$$\cup \cap := \cup \cap = \cup \cap.$$

Additional relations

For simplicity, we will assume throughout that $n \neq -2$.

One can already show that we have a **full** functor

$$\mathcal{T} \rightarrow \mathfrak{f}\text{-mod.}$$

But the functor is certainly **not faithful**. So we need to impose more relations on morphisms in \mathcal{T} .

Let's focus on the space $\text{Hom}_{\mathfrak{f}}(V^{\otimes 2}, V^{\otimes 2})$.

Use two facts

- 1 The kernel of the functor $\mathcal{T} \rightarrow \mathfrak{f}\text{-mod}$ is a **tensor ideal** (i.e. closed under tensor product and composition).
- 2 We know $\dim \text{Hom}_{\mathfrak{f}}(V^{\otimes 2}, V^{\otimes 2}) = 5$.

Rotation and switch

Consider the linear operators

$$\text{Rot}: \text{Hom}(I^{\otimes 2}, I^{\otimes 2}) \rightarrow \text{Hom}(I^{\otimes 2}, I^{\otimes 2}), \quad \text{Rot} \left(\begin{array}{|c|} \hline \boxed{f} \\ \hline \end{array} \right) = \begin{array}{|c|} \hline \boxed{f} \\ \hline \end{array} \text{ with a rotation arrow},$$

$$\text{Switch}: \text{Hom}(I^{\otimes 2}, I^{\otimes 2}) \rightarrow \text{Hom}(I^{\otimes 2}, I^{\otimes 2}), \quad \text{Switch} \left(\begin{array}{|c|} \hline \boxed{f} \\ \hline \end{array} \right) = \begin{array}{|c|} \hline \boxed{f} \\ \hline \end{array} \text{ with a switch arrow},$$

In other words,

$$\begin{aligned} \text{Rot}(f) &= (\cap \otimes 1_1^{\otimes 2}) \circ (1_1 \otimes f \otimes 1_1) \circ (1_1^{\otimes 2} \otimes \cup), \\ \text{Switch}(f) &= f \circ \times. \end{aligned}$$

Any tensor ideal of \mathcal{T} or \mathcal{F} is **invariant** under Rot and Switch.

In particular, the kernel of the functor $\mathcal{T} \rightarrow \mathfrak{f}\text{-mod}$ is invariant under Rot and Switch.

Rotation and switch

The operators Rot and Switch generate an action of \mathfrak{S}_3 on the 6-dimensional space spanned by

$$||, \cup, \times, \succ, \prec, \otimes := \begin{array}{c} \diagup \\ \diagdown \end{array}.$$

More precisely, one can show (using only relations in \mathcal{T}) that

$$\begin{aligned} \text{Rot}(| |) &= \cup, & \text{Rot}(\cup) &= | |, & \text{Rot}(\times) &= \times, \\ \text{Rot}(\succ) &= \prec, & \text{Rot}(\prec) &= \succ, & \text{Rot}(\otimes) &= \otimes, \end{aligned}$$

and

$$\begin{aligned} \text{Switch}(| |) &= \times, & \text{Switch}(\times) &= | |, & \text{Switch}(\cup) &= \cup, \\ \text{Switch}(\succ) &= \otimes, & \text{Switch}(\otimes) &= \succ, & \text{Switch}(\prec) &= \prec. \end{aligned}$$

Deducing the relations

Since $\dim \text{Hom}(V^{\otimes 2}, V^{\otimes 2}) = 5$, we want a linear dependence relation on the morphisms

$$||, \cup, \times, \text{Y-shape}, \text{X-shape}, \text{X-shape with dot}.$$

Key question: How do we figure out this relation **without** doing explicit computations in $\mathfrak{f}\text{-mod}$?

Key idea: Since the kernel of the functor $\mathcal{F} \rightarrow \mathfrak{f}\text{-mod}$ is invariant under Rot and Switch, our relation must be an **eigenvector** for these operators. (Otherwise our space of relations would be too big.)

The space of simultaneous eigenvectors for **both** Rot and Switch is spanned by

$$|| + \cup + \times \quad \text{and} \quad \text{Y-shape} + \text{X-shape} + \text{X-shape with dot}.$$

So our relation must be some linear combination of these two.

Deducing the relation

If

$$|| + \cup + \times = 0,$$

then composing on bottom with \cup yields $(n+2)\cup = 0$. But then

$$| = \cup = 0,$$

and so the category becomes trivial.

So we want a relation of the form

$$\times + \times + \times = \lambda (|| + \cup + \times).$$

Composing on the bottom with \cup gives

$$2\alpha\cup = \lambda(n+2)\cup \quad \text{and so} \quad \lambda = \frac{2\alpha}{n+2}.$$

Additional relations

Since $\dim \text{Hom}_f(V^{\otimes 2}, V^{\otimes 2}) = 5$, we also want a linear dependence relation on the morphisms

$$||, \cup, \times, \succ, \prec, \square.$$

A similar analysis shows that the relation must be

$$\square = \frac{\alpha^2(n+14)}{2(n+2)^2} (|| + \cup) + \frac{\alpha(n-6)}{2(n+2)} (\succ + \prec) + \frac{3\alpha^2(2-n)}{2(n+2)^2} \times.$$

Finally, using $\dim \text{Hom}_f(V^{\otimes 2}, V^{\otimes 3}) = 15$, we can deduce the relation

$$\begin{aligned} \text{pentagon} &= \frac{\alpha(10-n)}{4(n+2)} (\text{pentagon}_1 + \text{pentagon}_2 + \text{pentagon}_3 + \text{pentagon}_4 + \text{pentagon}_5) \\ &\quad - \frac{\alpha^2(n+30)}{8(n+2)^2} (\cup + || + \prec + \succ) \\ &\quad + \frac{3\alpha^2(n-2)}{8(n+2)^2} (\text{pentagon}_6 + \text{pentagon}_7 + \text{pentagon}_8 + \text{pentagon}_9 + \text{pentagon}_{10}). \end{aligned}$$

Definition of the category \mathcal{F}

The category $\mathcal{F} = \mathcal{F}_{\alpha,n}$ is obtained from $\mathcal{T}_{\alpha,n}$ by imposing three additional relations:

$$\begin{array}{c} \diagup \diagdown + \diagdown \diagup + \diagup \diagup \diagdown \diagdown = \frac{2\alpha}{n+2} \left(\parallel \parallel + \cup \cup + \times \times \right), \end{array}$$

$$\begin{array}{c} \square = \frac{\alpha^2(n+14)}{2(n+2)^2} \left(\parallel \parallel + \cup \cup \right) + \frac{\alpha(n-6)}{2(n+2)} \left(\diagup \diagdown + \diagdown \diagup \right) + \frac{3\alpha^2(2-n)}{2(n+2)^2} \times \times, \end{array}$$

$$\begin{array}{c} \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \\ \diagup \diagdown \\ \diagdown \diagup \end{array} = \frac{\alpha(10-n)}{4(n+2)} \left(\begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \\ \diagup \diagdown \\ \diagdown \diagup \end{array} + \begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \\ \diagdown \diagup \\ \diagup \diagdown \end{array} + \begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \\ \diagdown \diagup \\ \diagup \diagdown \end{array} + \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \\ \diagup \diagdown \\ \diagdown \diagup \end{array} + \begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \\ \diagdown \diagup \\ \diagup \diagdown \end{array} \right) \\ - \frac{\alpha^2(n+30)}{8(n+2)^2} \left(\begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \end{array} + \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} + \begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \end{array} + \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} + \begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \end{array} \right) \\ + \frac{3\alpha^2(n-2)}{8(n+2)^2} \left(\begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} + \begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \end{array} + \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} + \begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \end{array} + \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} \right). \end{array}$$

Theorem (Gandhi–S.–Zaynullin 2021)

- 1 There is a monoidal functor

$$\Phi: \mathcal{F}_{7/3,26} \rightarrow \mathfrak{f}\text{-mod}, \quad I \mapsto V.$$

- 2 The functor Φ is **full** (surjective on morphisms).
- 3 Passing to the **additive Karoubi envelope** (idempotent completion of the additive envelope) yields a functor

$$\text{Kar}(\Phi): \text{Kar}(\mathcal{F}_{7/3,26}) \rightarrow \mathfrak{f}\text{-mod}.$$

that is **essentially surjective** (i.e. every f.d. \mathfrak{f} -module is isomorphic to an object in the image of $\text{Kar}(\Phi)$).

Remarks

Remark

The functor Φ can be described explicitly using the **Albert algebra**, which is the unique exceptional Jordan algebra.

Remark

The relation

$$\begin{array}{c} \diagup \quad \diagdown \\ \diagdown \quad \diagup \end{array} + \begin{array}{c} \diagdown \quad \diagup \\ \diagup \quad \diagdown \end{array} + \begin{array}{c} \diagdown \quad \diagdown \\ \diagup \quad \diagup \end{array} = \frac{2\alpha}{n+2} \left(\begin{array}{c} | \\ | \end{array} + \begin{array}{c} \cup \\ \cap \end{array} + \begin{array}{c} \times \\ \times \end{array} \right)$$

corresponds to the **Cayley–Hamilton equation** for traceless 3×3 octonionic matrices.

The upshot

Since

$$\mathrm{Kar}(\Phi): \mathrm{Kar}(\mathcal{F}_{7/3,26}) \rightarrow \mathfrak{f}\text{-mod}$$

is full and essentially surjective,

$\mathfrak{f}\text{-mod}$ is a quotient of $\mathrm{Kar}(\mathcal{F}_{7/3,26})$.

Philosophy

All homomorphisms between f.d. \mathfrak{f} -modules are built from the “flip” symmetry, the bilinear form (and its dual), and a trilinear form (or the multiplication in the Albert algebra).

Question

Is the functor $\mathrm{Kar}(\Phi)$ faithful, and hence an equivalence of categories, or are there further relations?

Quantization

One can repeat the strategy for the **quantized enveloping algebra** $U_q(\mathfrak{f})$.

The main idea is that we move from **symmetric monoidal categories** to **braided monoidal categories**.

So we replace the flip \times with two morphisms

$$\times, \times : I \otimes I \rightarrow I \otimes I,$$

that are mutually inverse and satisfy the braid relations:

$$\begin{array}{c} \diagup \\ \diagdown \end{array} = \begin{array}{c} | \\ | \end{array} = \begin{array}{c} \diagdown \\ \diagup \end{array}, \quad \begin{array}{c} \diagup \\ \diagdown \end{array} \begin{array}{c} \diagdown \\ \diagup \end{array} = \begin{array}{c} \diagdown \\ \diagup \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array}.$$

Quantum diagrammatic category

Let \mathcal{F}_q be the $\mathbb{Q}(q)$ -linear strict monoidal category generated by the object $\mathbb{1}$ and generating morphisms

$$\cup: \mathbb{1} \otimes \mathbb{1} \rightarrow \mathbb{1}, \quad \times, \times: \mathbb{1} \otimes \mathbb{1} \rightarrow \mathbb{1} \otimes \mathbb{1}, \quad \cup: \mathbb{1} \rightarrow \mathbb{1} \otimes \mathbb{1}, \quad \cap: \mathbb{1} \otimes \mathbb{1} \rightarrow \mathbb{1},$$

subject to the following relations:

$$\cup = | = \cup, \quad \cup := \cup = \cup, \quad \cap = \cap, \quad \cap = \cap,$$

$$\cap = | | = \cap, \quad \cap = \cap, \quad \cup = \cup, \quad \cap = \cup,$$

$$\cap = q^{24} \cap, \quad \cup = q^{12} \cup, \quad \cap = \frac{[2][7][12]}{[4][6]} |,$$

$$\bigcirc = \frac{[3][8][13][18]}{[4][6][9]} \mathbb{1}_{\mathbb{1}}, \quad \bigcirc = 0, \quad \text{where } [n] = \frac{q^n - q^{-n}}{q - q^{-1}},$$

(cont. on next page)

Quantum diagrammatic category (cont.)

$$\times - \times = \frac{q^{-4} - q^4}{[3]} \left(\parallel - \cup + \succ - \swarrow \right),$$

$$q^6 \begin{array}{c} \diagup \\ \diagdown \end{array} = \frac{1}{q^2 + q^{-2}} \left(q^{-8} \parallel + q^8 \cup + \times \right) - q^{-2} \succ - q^2 \swarrow,$$

$$\begin{array}{c} \diagup \\ \square \\ \diagdown \end{array} = \frac{q^{10} + q^8 + q^6 + q^4 + 1}{q^4(q^4 + 1)^2} \parallel + \frac{q^2(q^{10} + q^6 + q^4 + q^2 + 1)}{(q^4 + 1)^2} \cup \\ - \frac{[2][3][6]}{[4]^2} \times + \frac{q^{10} + 2q^6 + q^2 + 1}{q^8 + q^4} \succ + \frac{q^{10} + q^8 + 2q^4 + 1}{q^6 + q^2} \swarrow,$$

$$\begin{array}{c} \diagup \\ \square \\ \diagdown \end{array} = - \left(\begin{array}{c} \diagup \\ \diagdown \\ \diagup \\ \diagdown \end{array} + \begin{array}{c} \diagdown \\ \diagup \\ \diagdown \\ \diagup \end{array} + \begin{array}{c} \diagdown \\ \diagup \\ \diagup \\ \diagdown \end{array} + \begin{array}{c} \diagup \\ \diagdown \\ \diagup \\ \diagup \end{array} + \begin{array}{c} \diagup \\ \diagdown \\ \diagdown \\ \diagdown \end{array} \right) \\ - \frac{[7]}{[4]^2} \left(\begin{array}{c} \diagdown \\ \cup \end{array} + \begin{array}{c} \diagup \\ \cup \end{array} + \begin{array}{c} \diagdown \\ \cup \end{array} + \begin{array}{c} \diagup \\ \cup \end{array} \right) \\ + \frac{[3]^2}{[4]^2} \left(\begin{array}{c} \cup \\ \diagdown \end{array} + \begin{array}{c} \cup \\ \diagup \end{array} + \begin{array}{c} \cup \\ \diagdown \end{array} + \begin{array}{c} \cup \\ \diagup \end{array} + \begin{array}{c} \cup \\ \diagdown \end{array} \right).$$

Theorem (S.–Westbury 2022)

- 1 There is a monoidal functor

$$\Phi_q: \mathcal{F}_q \rightarrow U_q(\mathfrak{f})\text{-mod}, \quad \mathbb{1} \mapsto V_q,$$

where V_q is the quantum analogue of V .

- 2 The functor Φ_q is **full** (surjective on morphisms).
- 3 Passing to the **additive Karoubi envelope** (idempotent completion of the additive envelope) yields a functor

$$\text{Kar}(\Phi_q): \text{Kar}(\mathcal{F}_q) \rightarrow U_q(\mathfrak{f})\text{-mod}.$$

that is **essentially surjective** (i.e. every type $\mathbb{1}$ f.d. $U_q(\mathfrak{f})$ -module is isomorphic to an object in the image of $\text{Kar}(\Phi_q)$).

Summary

Comparison to other types

- \mathcal{F} is a type F_4 analogue of the **Brauer category**.
- \mathcal{F}_q is a type F_4 analogue of the **framed HOMFLYPT skein category** (type A), the **Kauffman category** (types BCD), and Kuperberg's G_2 category.

Endomorphism algebras

$\text{End}_{\mathcal{F}}(\mathbb{I}^{\otimes r})$ is a type F_4 analogue of the **Brauer algebra**.

We now have diagrammatic tools to study representation theory in type F_4 .
